

Waves

Reflection, Refraction, Diffraction, and Interference

Objectives

- ◆ Understand how water depth affects amplitude and wavelength
- ◆ Understand how media changes wave speed
- ◆ Recognize and describe the properties of:
 - ◆ Wave reflection
 - ◆ Wave refraction
 - ◆ Wave diffraction
 - ◆ Wave interference

Wave Reflection

Where have you experienced waves reflecting?

- ◆ Echoes
- ◆ Radio waves
- ◆ Bats

Wave Reflection

- ◆ Waves reflect like billiard (pool) balls

Wave Reflection

- ◆ Waves at right angles
- ◆ Waves at oblique angles

Wave Reflection (Ray Diagram)

Wave Refraction

When waves pass from 1 medium to another:

1. The wave velocity changes
2. The wave direction changes

Wave Refraction

Where do waves move from one medium to another?

- ◆ Light from cold air to warm air
- ◆ Light from space to air
- ◆ Light from water to air

Wave Refraction

- ◆ Water passes from deep water to shallow water - Wavelength shortens

Wave Refraction

- ◆ No matter what the medium the frequency doesn't change:

$$f_1 = f_2$$

Wave Refraction

- ◆ Oblique waves bend towards the normal when entering slower medium
- ◆ Oblique waves bend away from the normal when entering faster medium

Wave Refraction

When waves enter shallow water (lower speed medium) they bend towards the normal (become more parallel to shore)

Wave Diffraction - Particles

Wave Diffraction - Waves

Wave Diffraction

- Shorter incident wavelengths are diffracted less
- Longer incident wavelengths are diffracted more

Wave Diffraction

Short wavelengths diffract less around an object

Long wavelengths diffract more around an object

Wave Diffraction

- Waves passing through smaller openings are diffracted more
- Waves passing through larger openings are diffracted less

Wave Interference

- Waves rarely occur just by themselves
- Usually we have many waves occurring

Wave Interference

What happens when two waves meet one another?

- ◆ Bounce off each other?
- ◆ Die immediately?
- ◆ Pass through one another?
- ◆ Something else?

** The waves pass through one another, but create interference

Wave Interference

- ◆ Interference doesn't affect the individual waves
- ◆ Interference only affects the individual particles of the medium
- ◆ Interference only affects **amplitude**

Wave Interference

Constructive Interference:

- ◆ 2 waves with positive amplitude
- ◆ 2 waves with negative amplitude

Resulting wave amplitude will be larger than original wave amplitudes

Wave Interference

Constructive Interference:

Wave Interference

Destructive Interference:

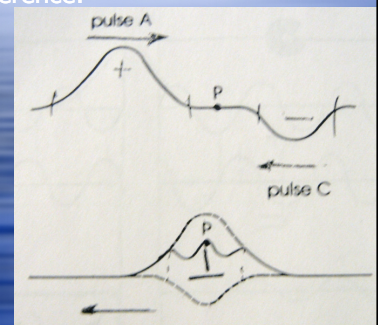

- ◆ One positive amplitude wave, one negative amplitude wave

Resulting wave amplitude will be smaller than original wave amplitudes

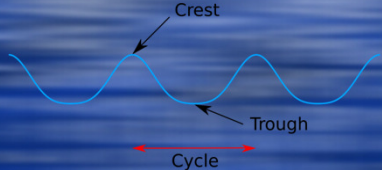

Wave Interference

Destructive Interference:

Principle of Superposition

- Wave amplitude = displacement of its individual particles from rest position
- Crest created from +ve displacement
- Trough created from -ve displacement

The diagram shows a blue sinusoidal wave. A red double-headed arrow below the wave is labeled 'Cycle'. An arrow points to the highest point of the wave, labeled 'Crest'. Another arrow points to the lowest point of the wave, labeled 'Trough'.

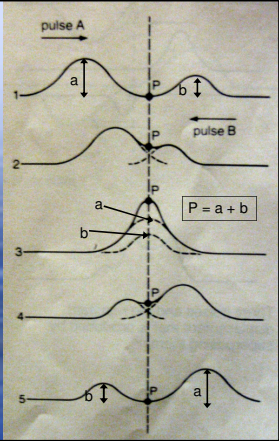

Principle of Superposition

Particle displacement of wave 1
+ Particle displacement of wave 2
Resultant particle displacement

Principle of Superposition

- Constructive Interference

$(\text{Wave amplitude})_P = (\text{Wave amplitude})_A + (\text{Wave amplitude})_B$

The diagram shows five stages of two pulses, 'pulse A' and 'pulse B', moving towards each other. Stage 1 shows pulse A on the left and pulse B on the right. Stage 2 shows them overlapping. Stage 3 shows the resulting pulse with a larger amplitude, labeled $P = a + b$. Stage 4 shows them separating. Stage 5 shows pulse A on the left and pulse B on the right again.

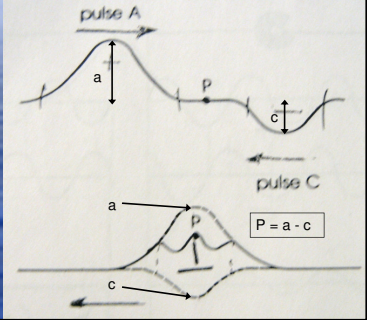

Principle of Superposition

- Destructive Interference

$(\text{Wave amplitude})_P = (\text{Wave amplitude})_A + (\text{Wave amplitude})_C$

But a trough has a negative amplitude

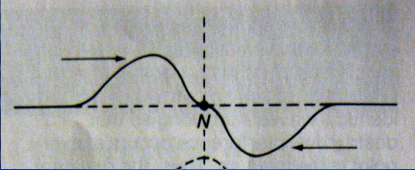

$P = a - c$

The diagram shows three stages of two pulses, 'pulse A' and 'pulse C', moving towards each other. Stage 1 shows pulse A on the left and pulse C on the right. Stage 2 shows them overlapping, with pulse C being a trough where pulse A is a crest. Stage 3 shows the resulting pulse with a smaller amplitude, labeled $P = a - c$.

Standing Waves

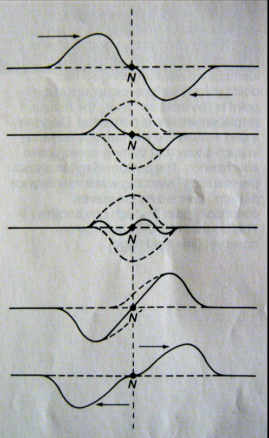

- A special case of wave interference
- 2 waves (same wavelength/amplitude) traveling in opposite directions, creates a standing wave

The diagram shows two waves traveling in opposite directions, one to the right and one to the left. They are shown as a solid line and a dashed line. A vertical dashed line marks a point where the two waves are always out of phase, labeled 'N' for Node.

Standing Waves

- When 2 like waves meet (Same A & λ), There is a point that never moves.
- This point is called a Node

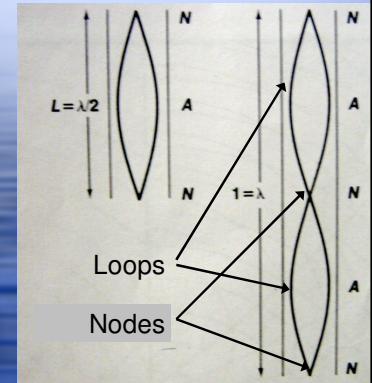

The diagram shows two waves traveling in opposite directions, one to the right and one to the left. They are shown as a solid line and a dashed line. A vertical dashed line marks a point where the two waves are always in phase, labeled 'N' for Node.

Standing Wave

- ◆ Where do like waves (same A & λ) commonly meet?
- ◆ Standing waves are commonly found when a wave meets its reflection (Echo)
- ◆ Incident (A & λ) = Reflected (A & λ) but are headed in opposite directions

Standing Waves

Homework

- ◆ Reflection, Refraction, and Diffraction worksheet
